

What the instrumented gene marks: a definable anabolic state, not a restatement of activation strength

Panels c and d characterise the chromatin of the axis. They are NOT the claim, withdrawn during revision, that the instrument acts by disrupting an AP-1 motif — that test returned an empirical $P = 1.0$ and is reported nowhere in this paper. Rebuilt without TPI1, which had entered both the defining score and the enrichment family, the glycolysis enrichment is 21.0-fold on 14 genes against 21.3 on 15.
