

Every cell beats its comparators, but rheumatoid arthritis beats them by the narrowest margin in the grid

Each row is one cell, scored against every reference list in the study with ≥ 30 placeable lead SNPs. A post-hoc diagnostic (S39), not a registered test, and not used to upgrade any cell. Cancer cells span 1.82- to 7.63-fold over their largest comparator; the two RA cells sit at 1.28 and 1.32. Of the four comparators available for RA, two leave the cell standing — prostate (1.04 $\times$, $P = 0.59$) and melanoma (1.71 $\times$, $P = 0.10$), the one this study designated — while HCC (3.05 $\times$, $P = 0.0028$) and colorectal (1.77 $\times$, $P = 0.0045$) would each have voided it. Whether the cell survives depends on which comparator was named.
