

Scored against four unrelated diseases, the cancer cells win by an unbounded margin and rheumatoid arthritis by a quarter

Each row is one cell of the grid, scored against every reference list in the study with ≥ 30 placeable lead SNPs (S39). Four cancer cells have no unrelated list enriching at all. On RA the list this study designated as its mismatched control (melanoma, $1.71\times$, $P = 0.10$) is the most favourable of the four; HCC's gives $3.05\times$ ($P = 0.0028$) and would have voided the cell. A single-list negative control returns a verdict about the list as much as about the attribution.
