

Present in each cohort, confirmed in none twice

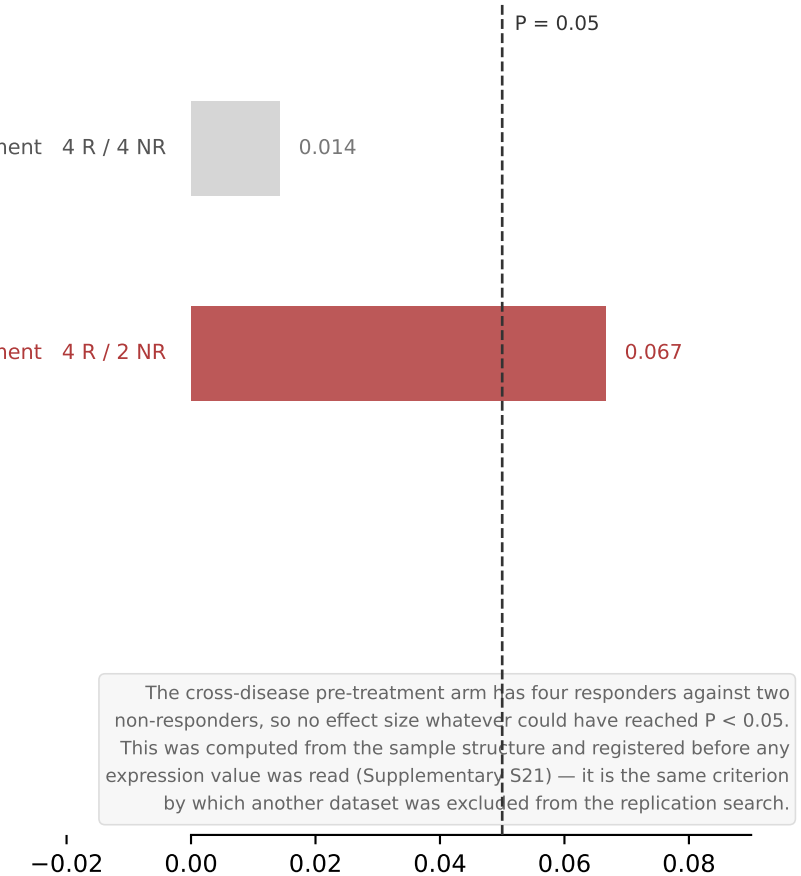

Both arms significant on discovery · no arm confirmed a second time · the two follow-ups fail in mirror image

a The same pre-specified test in three cohorts

Composite signature score, non-responders minus responders

b What the cross-disease design could have shown at all

Smallest one-sided permutation P the design can produce

The cross-disease pre-treatment arm has four responders against two non-responders, so no effect size whatever could have reached $P < 0.05$. This was computed from the sample structure and registered before any expression value was read (Supplementary S21) — it is the same criterion by which another dataset was excluded from the replication search.
